BONAFIDE CERTIFICATE

This is to certify that **Miss. Harshada Mahendra Kumbhar** PRN 2024052569, is a bonafide student of B.Sc. III (Computer Science), Semester V, of this college during the academic year 2026 – 2027.

She has successfully completed the On Job Training (OJT) of 60 hours (4 Credits) as per the curriculum prescribed by Shivaji University, Kolhapur, at **IBase Electrosoft LLP (Branch Pune)** during the period **20th July 2026** to **20th September 2026** and has submitted this report titled "Report on On Job Training" in partial fulfilment of the requirement for Semester V.

This report is a record of work carried out by the student and has not been submitted elsewhere for the award of any other degree or diploma.

OJT Coordinator **Head, Department of Computer Science**

Name: _____

External Examiner

DECLARATION

I, HARSHADA MAHENDRA KUMBHAR, hereby declare that this report entitled “Report on On Job Training” submitted for Semester V, B.Sc. (Computer Science), is a record of genuine work carried out by me at **IBase Electrosoft LLP (Branch Pune)** during the period **20th July 2026** to **20th September 2026**, under the guidance of Miss. P. B. Gaikwad and Mr. Nakul Deshmukh.

I further declare that this report is the result of my own work and has not been submitted, in part or full, to this or any other University/Institute for the award of any degree or diploma.

DATE:

PLACE: Islampur

Student Name	No	Signature
HARSHADA MAHENDRA KUMBHAR		

ACKNOWLEDGEMENT

I take this opportunity to express my sincere gratitude to **IBase Electrosoft LLP (Branch Pune)** for providing me the opportunity to undergo On Job Training and gain valuable industrial exposure.

I am deeply thankful to **Mr. Nakul Deshmukh, CEO**, for his constant guidance, encouragement, and support throughout the training period, and for patiently clarifying my doubts.

I would also like to thank Miss. P. B. Gaikwad, Department of Computer Science for his/her valuable guidance and for facilitating this OJT as part of the Semester V curriculum of Shivaji University, Kolhapur.

I extend my sincere thanks to the Principal Dr. A. M. Jadhav and the Head of the Department of Computer Science Mr. N. R. Jagatap for their continuous support and for granting permission to undertake this training.

Finally, I am grateful to my family and friends for their constant encouragement and support throughout this training and the preparation of this report.

HARSHADA MAHENDRA KUMBHAR

INTRODUCTION :

The Online Vegetable Store Using API is a web-based application designed to make the process of buying fresh vegetables easy, convenient, and efficient. In today's digital world, online shopping has become an important part of daily life. People prefer online services because they save time, reduce physical effort, and provide easy access to products from anywhere. This project aims to provide a digital platform where customers can browse different types of vegetables, check their prices, view product details, and place orders online without visiting a physical vegetable market.

The main objective of this project is to connect customers with vegetable sellers through an online platform. The application provides a user-friendly interface that allows customers to explore a variety of fresh vegetables, such as potatoes, tomatoes, onions, carrots, cabbage, cauliflower, spinach, and other seasonal vegetables. Customers can select their required vegetables, add them to a shopping cart, update quantities, calculate the total price, and proceed with the checkout process.

Application Programming Interface (API) plays an important role in this project. APIs allow different parts of the application to communicate with each other and exchange data. For example, a product API can retrieve vegetable names, prices, descriptions, images, and availability details from a database or backend server. An order API can send customer order information to the server, while other APIs can support user authentication, payment processing, and delivery tracking. The exact APIs used depend on the technologies and services selected during development.

The system can include important features such as user registration, login, vegetable search, category-wise product browsing, shopping cart management, order placement, and order history. An administrator can manage vegetable details, update prices, add new products, monitor stock availability, and manage customer orders. These features help improve the efficiency of vegetable store operations and make product management easier.

The application also helps reduce the limitations of traditional vegetable shopping. Customers may face problems such as long queues, limited shopping time, difficulty comparing prices, and inconvenience in travelling to local markets. Through the online vegetable store, customers can view available products and their prices in one place and place orders according to their requirements. The system can also be designed to provide notifications about order confirmation, delivery status, and product availability.

This project can be developed using technologies such as HTML, CSS, and JavaScript for the frontend, along with a backend framework such as Node.js, PHP, Python, or Java. A database such as MySQL or MongoDB can be used to store customer information, vegetable details, inventory records, and order information. APIs connect the frontend and backend, helping the application exchange data efficiently and maintain consistency across its different modules.

In conclusion, the Online Vegetable Store Using API is a useful application that combines online shopping technology with vegetable retail management.

It provides customers with a convenient way to purchase vegetables and gives sellers an organized method of managing products, stock, and orders. The project demonstrates how web development, database management, and API integration can be used to develop a practical solution for everyday shopping needs. In the future, the application can be enhanced with online payment gateways, location-based delivery, personalized recommendations, real-time inventory updates, and mobile application support.

THEME OF PROJECT :

The theme of the Online Vegetable Store Using API project is to develop a user-friendly online platform that allows customers to browse, select, and purchase fresh vegetables through the internet. The main aim of this project is to simplify the process of buying vegetables by providing a convenient digital shopping experience. Customers can view different types of vegetables, check their prices, explore product details, add items to their shopping cart, and place orders without visiting a physical vegetable market.

The system uses Application Programming Interfaces (APIs) to exchange data between the application and external or backend services. APIs can be used to retrieve vegetable information, display product prices, manage customer orders, process payments through supported payment services, and provide delivery-related information. This helps make the application more efficient, flexible, and capable of handling updated information.

The project focuses on bringing traditional vegetable shopping into the digital world. It aims to save customers time and effort while making vegetable shopping more accessible. Users can search for vegetables, compare prices, select the required quantities, and manage their purchases from their homes using a computer or mobile device.

Another important aspect of the project is the management of vegetable products by the administrator. The administrator can add new vegetables, update product details and prices, manage available stock, and view customer orders. These features help maintain accurate product information and improve the overall shopping experience.

The Online Vegetable Store Using API project also emphasizes ease of use, data accuracy, security, and efficient communication between different application components. Depending on the APIs and services integrated into the system, it can support online payments, order tracking, delivery updates, and customer notifications.

In conclusion, the theme of this project is to create a modern, convenient, and efficient online vegetable shopping system by combining web or mobile application technology with API integration. It provides a practical solution for customers and vegetable sellers by reducing manual effort, improving product accessibility, and supporting the digital transformation of the vegetable retail business.

MOTIVATION OF THE PROJECT :

The main motivation behind developing the Online Vegetable Store Using API project is to make the process of purchasing fresh vegetables easier, faster, and more convenient for customers. In today's busy lifestyle, many people find it difficult to visit traditional vegetable markets regularly because of time constraints, traffic, long queues, and busy work schedules. An online vegetable store provides a digital platform where customers can browse different vegetables, check their prices, view product details, and place orders from the comfort of their homes.

Traditional vegetable shopping often requires customers to visit physical markets to compare prices and check availability. Sometimes, the required vegetables may not be available, or customers may have to spend extra time searching for suitable products. The proposed system aims to reduce these difficulties by providing an organized online shopping experience. Customers can easily explore available vegetables, select the required quantities, add products to their shopping cart, and proceed with the ordering process.

Another important motivation for this project is the use of Application Programming Interfaces (APIs) to improve communication between different parts of the application. APIs help the frontend interact with the backend and retrieve information such as vegetable names, prices, product images, availability, and order details. Depending on the system design, APIs can also support user authentication, payment processing, delivery tracking, and other useful services. This makes the application more flexible, efficient, and easier to maintain.

The project is also motivated by the increasing use of smartphones, computers, and internet-based services in everyday life. Online shopping has become a common way to purchase various products, and vegetables can also be made available through a similar digital platform. By developing this system, the project aims to provide a simple and user-friendly interface that can be used by people with different levels of technical knowledge.

Furthermore, the system can help vegetable sellers and small business owners expand their businesses beyond local physical markets. Sellers can display their products online, update prices, manage available stock, and receive customer orders through a centralized platform. This can improve the management of daily sales and help sellers reach more customers. It may also reduce some of the manual work involved in maintaining product lists and recording orders.

The project also focuses on improving transparency in vegetable shopping. Customers can view product information and prices before placing an order, helping them make informed purchasing decisions. A properly implemented inventory management system can help ensure that displayed stock information remains up to date and reduce the chances of customers ordering unavailable products.

Another motivation is to develop practical knowledge of modern web development technologies. Through this project, students can learn how to design a user interface, integrate APIs, retrieve and display data, manage shopping cart operations, validate user inputs, and handle customer orders. It provides practical experience in frontend development, backend communication, database management, and software testing.

In addition, the project encourages the digital transformation of small-scale vegetable businesses. By introducing online ordering and digital product management, the system can provide an alternative to traditional shopping methods and help businesses adapt to changing customer expectations. Features such as product search, category filtering, order history, and delivery information can further improve the overall shopping experience.

In conclusion, the motivation for developing the Online Vegetable Store Using API project is to create a convenient, reliable, and efficient platform for buying and selling vegetables online. The system aims to save customers time, simplify the shopping process, support vegetable sellers, and demonstrate the practical application of API integration in web development. It represents a useful step toward making everyday grocery shopping more accessible through modern technology.

PROBLEM STATEMENT:

In today's fast-paced world, purchasing fresh vegetables from traditional markets can be time-consuming and inconvenient for many people. Customers often need to visit local vegetable shops, wait in queues, compare prices manually, and carry vegetables home. They may also face problems such as limited product availability, lack of updated price information, difficulty finding fresh vegetables, and the inconvenience of shopping during busy hours.

Traditional vegetable stores generally manage their products, stock, prices, and customer orders manually. This can lead to errors in inventory management, incorrect price information, delays in order processing, and difficulties in maintaining accurate records. Customers may not know which vegetables are available before visiting the store, while shopkeepers may find it challenging to manage large numbers of orders efficiently.

To overcome these problems, the Online Vegetable Store Using API project aims to develop a user-friendly online platform that allows customers to browse available vegetables, view product details, check prices, add items to a shopping cart, and place orders conveniently through a website or application. The system uses Application Programming Interfaces (APIs) to exchange data between the frontend and backend and, where required, to integrate services such as payment processing, delivery tracking, or product information.

The proposed system helps store administrators manage vegetable details, update prices, monitor stock availability, and process customer orders efficiently. It can also provide customers with a simple and convenient shopping experience by displaying updated information retrieved from the server.

The main objective of this project is to reduce the difficulties associated with traditional vegetable shopping, improve order management, save customers' time, and provide an efficient digital solution for purchasing vegetables online. By using APIs, the system can support reliable communication between different software components and can be extended with additional features in the future.

Thus, the Online Vegetable Store Using API project provides a convenient, accessible, and organized approach to buying and selling vegetables while improving the efficiency of both customers and store administrators.

METHOD USED :

The Online Vegetable Store Using API is a web-based application developed to make purchasing fresh vegetables easier, faster, and more convenient. The system allows customers to view available vegetables, check their prices, add products to a shopping cart, and place orders online. The application uses APIs (Application Programming Interfaces) to exchange data between the frontend, backend, database, and external services when required.

The main objective of this project is to reduce the effort involved in traditional vegetable shopping and provide a simple online platform where customers can purchase vegetables from their homes.

1. Requirement Analysis

The first step in developing the application is requirement analysis. In this stage, the functional and non-functional requirements of the system are identified.

Functional requirements:

- User registration and login.
- Displaying available vegetables with images, names, and prices.
- Searching and filtering vegetables.
- Viewing product details and availability.
- Adding and removing vegetables from the shopping cart.
- Calculating the total price of selected products.
- Placing orders and viewing order details.
- Allowing administrators to manage products, prices, stock, and orders.

Non-functional requirements:

- The application should be easy to use.
- Product information should be accurate and updated.
- The system should provide secure access to user information.
- The application should respond quickly to user requests.

2. System Design

After collecting the requirements, the overall architecture of the application is designed. The system can be divided into the following components:

Frontend: The frontend provides the user interface. It can be developed using HTML, CSS, JavaScript, React, or another suitable frontend technology. Customers use this interface to browse vegetables, manage their carts, and place orders.

Backend: The backend processes requests received from the frontend. It handles user authentication, product information, cart operations, order processing, and communication with the database.

Database: The database stores information such as user details, vegetable names, prices, stock quantities, shopping carts, and order records. MySQL, PostgreSQL, or MongoDB can be used.

API: APIs connect the frontend and backend and allow data to be transferred in a structured format, commonly JSON. REST APIs can be used to retrieve products, submit orders, and manage inventory.

3. API Integration

API integration is an important part of this project. APIs allow different components of the application to communicate with each other.

The application may use the following API endpoints:

- GET /API/vegetables – Retrieves the list of available vegetables.
- GET /API/vegetables/{id} – Retrieves details of a particular vegetable.
- POST /API/cart – Adds a vegetable to the shopping cart.
- PUT /API/cart/{id} – Updates the quantity of a cart item.
- DELETE /API/cart/{id} – Removes an item from the cart.
- POST /API/orders – Creates a new customer order.
- GET /API/orders – Retrieves the authenticated customer's orders.
- POST /API/login – Authenticates a user.

These are example endpoints; the actual endpoints depend on the backend implementation.

When a customer opens the vegetable store, the frontend sends a request to the product API. The backend retrieves the required information from the database and returns the response. The frontend then displays the vegetable details to the customer.

4. Product Management

The system maintains a list of vegetables with details such as product name, image, price, description, category, and available quantity.

The administrator can add new vegetables, update prices, change product information, and manage stock levels. The application retrieves the latest available product information through the API.

For example, when the price of tomatoes changes, the administrator updates the price through the product management interface. The updated information is saved in the database and can then be displayed to customers.

5. Shopping Cart Management

The shopping cart allows customers to select the vegetables they want to purchase. Customers can add products, change quantities, or remove items before placing an order.

The system calculates the subtotal using the product price and selected quantity.

Subtotal = Price per Unit × Quantity

For example, if a customer purchases 2 kg of tomatoes at ₹30 per kg, the subtotal is ₹60. The final order amount can also include delivery charges, discounts, or taxes if applicable.

The backend should validate product prices and stock quantities before accepting the order to prevent incorrect totals and purchases of unavailable products.

6. Order Processing

Once the customer has selected the required vegetables, the system allows them to proceed to checkout. The customer provides the necessary delivery details and selects an available payment method.

The backend validates the order information, checks product availability, calculates the final amount, and stores the order in the database. Stock quantities are updated after the order is successfully accepted.

The system can display an order confirmation containing the order number, selected vegetables, quantities, total amount, and order status.

If online payment is supported, a payment gateway API can be integrated to process payments securely. Otherwise, the application can provide cash on delivery if the store supports it.

7. Database Management

The database stores and manages all important application information. The main database tables or collections may include:

- Users: Stores customer names, email addresses, and securely managed authentication information.
- Vegetables: Stores product names, prices, descriptions, images, and stock quantities.
- Cart: Stores selected products and their quantities.
- Orders: Stores order numbers, customer references, totals, delivery information, and order status.
- Order Items: Stores the individual products included in each order.
- Payments: Stores payment references and statuses when payment functionality is implemented.

The backend communicates with the database and sends the required information to the frontend through APIs.

8. Testing

Testing is performed to ensure that the application works correctly and meets the project requirements.

The following types of testing can be carried out:

- Unit Testing: Tests individual functions, such as price calculations and product validation.

- Integration Testing: Checks communication between the frontend, backend, database, and APIs.
- Functional Testing: Verifies login, product search, cart management, checkout, and order placement.
- Usability Testing: Checks whether customers can easily understand and use the application.
- Security Testing: Checks authentication, access permissions, input validation, and protection of sensitive information.
- Performance Testing: Evaluates how the application responds when multiple users access it.

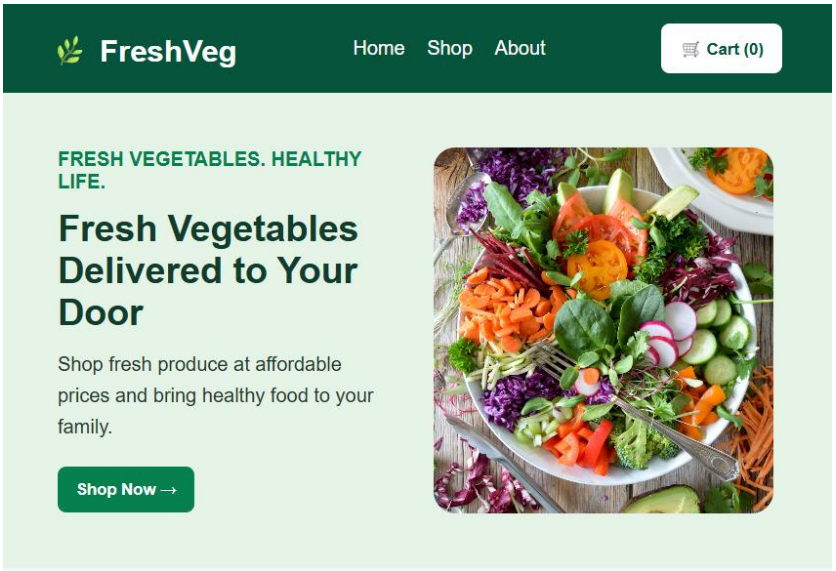

Errors identified during testing are corrected before the application is deployed.

9. Deployment and Maintenance

After successful testing, the application can be deployed to a web server or cloud hosting platform. The frontend, backend, and database are configured to work together in the production environment.

Regular maintenance is required to fix errors, update product information, monitor API performance, improve security, and introduce new features. API keys and other confidential credentials must be stored securely rather than exposed in public frontend code.

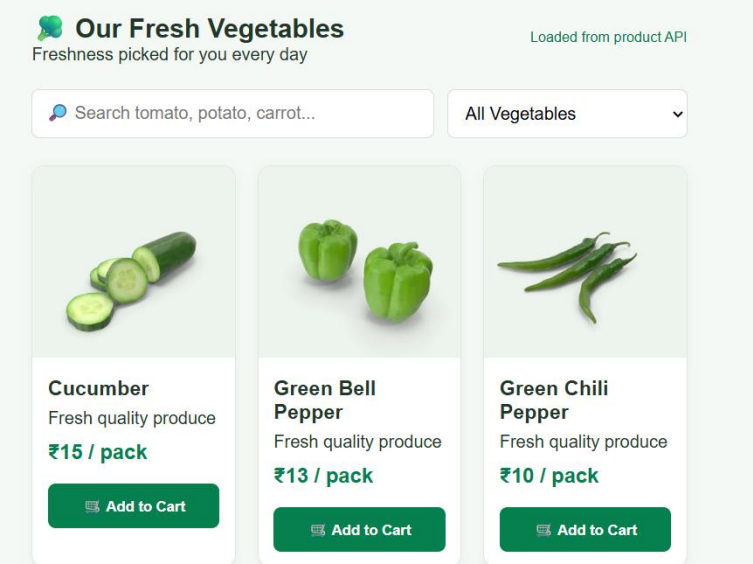

SCREENSHOT'S :

The screenshot shows the FreshVeg – Online Vegetable Store Using API website. It is designed to help customers buy fresh vegetables online at affordable prices.

Main features:

- Home: Displays the website's welcome page.
- Shop: Allows users to explore available vegetables.
- Cart: Shows the number of items added to the shopping cart.
- Search Bar: Helps users find vegetables such as tomatoes, potatoes, and carrots.
- Category Filter: Allows users to filter vegetables by category.
- API Integration: Loads vegetable product information dynamically from a product API.

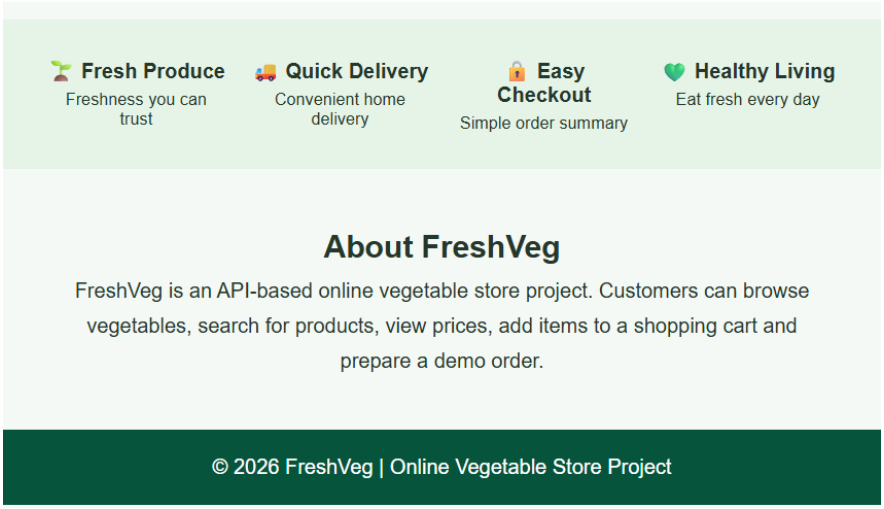

The screenshot shows an Online Vegetable Store web application that displays fresh vegetables using product API data. It provides a search bar to find vegetables and a category filter to select products. Each product card displays the vegetable image, name, description, price, and an Add to Cart button.

Examples of products shown are:

- Cucumber – ₹15/pack
- Green Bell Pepper – ₹13/pack
- Green Chili Pepper – ₹10/pack
- Potatoes – ₹23/pack

Main Purpose: The application helps users browse vegetables, check prices, search for products, and add items to **their** shopping cart easily.

The screenshot shows the FreshVeg – Online Vegetable Store Project, an API-based website for purchasing vegetables online. Customers can browse vegetables, view prices, search for products, add items to the shopping cart, and prepare a demo order. The website highlights fresh produce, quick delivery, easy checkout, and healthy living.

CONCLUSION

The Online Vegetable Store Using API project is designed to provide a convenient, efficient, and user-friendly platform for purchasing fresh vegetables online. The main objective of this project is to simplify the traditional vegetable shopping process by allowing customers to view available vegetables, check their prices, select the required quantities, and place orders through an online application. This system helps save time and effort while making vegetable shopping easier and more accessible.

The integration of Application Programming Interfaces (APIs) plays an important role in this project. APIs enable communication between different components of the application and help retrieve, send, and manage data efficiently. Depending on the implemented features, APIs can be used to manage vegetable details, product prices, customer information, shopping cart items, orders, and payment-related operations. This integration improves the functionality of the application and supports smooth data exchange between the frontend and backend systems.

The project provides several benefits, including easy product browsing, convenient ordering, improved data management, reduced manual work, and a better shopping experience for customers. It also helps vegetable sellers manage product availability and customer orders more effectively. The system can be accessed through a suitable web or mobile interface, allowing customers to shop from their homes without visiting a physical vegetable market.

Furthermore, this project provides practical knowledge of web development, API integration, database management, user interface design, and software testing. It demonstrates how modern technologies can be used to develop an online shopping application that addresses real-world problems.

In conclusion, the Online Vegetable Store Using API is a useful and practical project that connects technology with everyday shopping needs. Although the current system focuses on essential online shopping features, it has significant potential for future development. Features such as online payment integration, real-time delivery tracking, personalized recommendations, customer reviews, inventory alerts, and AI-based demand prediction can be added to improve its performance. Overall, the project offers a strong foundation for developing a more advanced, reliable, and scalable online vegetable shopping platform.

FUTURE ENHANCEMENTS :

The Online Vegetable Store Using API project can be improved in the future by adding advanced features and modern technologies to provide a better shopping experience for customers. The main aim of future enhancement is to make the system more efficient, secure, user-friendly, and reliable. These improvements will help customers purchase fresh vegetables online easily and help store owners manage their business effectively.

1. Online Payment Integration

In the future, the system can include secure online payment options such as UPI, debit cards, credit cards, and net banking. Customers will be able to complete their purchases without visiting the store physically. Payment gateway APIs can be integrated to process transactions securely and provide instant payment confirmation.

2. Real-Time Vegetable Price Updates

The system can use APIs to update vegetable prices dynamically. Customers will be able to view the latest prices, available quantities, and special offers. The store administrator can update prices according to market conditions, seasonal changes, and supplier rates.

3. Live Order Tracking

A live order tracking feature can be introduced to help customers check the current status of their orders. Customers will receive updates such as order confirmed, vegetables packed, out for delivery, and order delivered. GPS and mapping APIs can be integrated to improve delivery tracking.

4. AI-Based Vegetable Recommendations

Artificial Intelligence (AI) can be used to recommend vegetables based on customers' previous purchases, shopping habits, and preferences. For example, if a customer frequently buys tomatoes, potatoes, and onions, the system can suggest these vegetables during future visits. This feature can save time and make shopping more convenient.

5. Improved Inventory Management

The system can be enhanced with automatic stock management. When a customer purchases vegetables, the available quantity will be updated automatically. If a vegetable is out of stock, the system can display an unavailable message or suggest an alternative product. This will help store owners reduce errors and manage stock efficiently.

6. Mobile Application Development

In the future, the project can be developed into an Android or iOS mobile application. Customers will be able to browse vegetables, place orders, make payments, and receive notifications directly from their smartphones. A mobile application will make the online vegetable store more accessible and convenient.

7. Notifications and Alerts

Email, SMS, or push notification APIs can be integrated to send order confirmations, payment receipts, delivery updates, promotional offers, and special discounts. Customers can also receive alerts about new arrivals and seasonal vegetables.

8. Customer Reviews and Ratings

A review and rating system can be introduced so that customers can share their experiences regarding vegetable quality, freshness, packaging, and delivery services. These reviews will help other customers make better purchasing decisions and encourage store owners to improve their services.

9. Location-Based Delivery Services

Maps and location APIs can be used to identify customer addresses, calculate delivery distances, and find suitable delivery routes. The system can also show whether delivery is available in a particular area and estimate the expected delivery time.

10. Voice Search and Multilingual Support

The system can provide voice search so that customers can search for vegetables by speaking instead of typing. Support for multiple languages, including English, Hindi, and Marathi, can make the application easier to use for customers from different regions.

11. Enhanced Security and Data Protection

Future versions can include stronger authentication, encrypted communication, secure API access, and role-based access control. These features will help protect customer information, order details, and payment-related data from unauthorized access.

12. Customer Offers and Loyalty Programs

The system can introduce discount coupons, reward points, referral offers, and membership benefits. Regular customers can earn points on purchases and redeem them for discounts on future orders. This can improve customer satisfaction and encourage repeat purchases.

13. Demand Prediction and Waste Reduction

Data analytics and AI can be used to predict the demand for different vegetables based on previous sales, seasonal trends, and customer preferences. Store owners can use these predictions to purchase appropriate quantities, reduce food waste, and maintain a steady supply of fresh vegetables.

14. Subscription-Based Vegetable Delivery

Customers can subscribe to daily, weekly, or monthly vegetable delivery plans. They can select their preferred vegetables, quantities, and delivery schedules. This feature will be especially useful for families and customers who regularly purchase fresh vegetables.

15. Admin Dashboard and Sales Reports

An advanced administrator dashboard can be developed to display total sales, pending orders, available stock, popular vegetables, customer feedback, and delivery performance. Data visualization tools can help store owners analyze business performance and make better decisions.

REFERENCES :

The following references can be included in your college project report for “Online Vegetable Store Using API.” These references cover web development, API integration, database management, online shopping, payment processing, product information, and software testing.

1. Books and study materials

1. HTML and CSS: Design and Build Websites

- Author: Jon Duckett
- Publisher: Wiley
- Purpose: This book provides knowledge of HTML and CSS for designing the user interface of an online vegetable store. It helps with creating product cards, navigation menus, shopping pages, forms, and responsive layouts.

2. JavaScript and JQuery: Interactive Front-End Web Development

- Author: Jon Duckett
- Publisher: Wiley
- Purpose: This book helps explain JavaScript concepts used to make the website interactive, validate user input, update shopping cart quantities, calculate totals, and communicate with APIs.

3. Eloquent JavaScript

- Author: Marijn Haverbeke
- Publisher: No Starch Press
- Purpose: This book explains JavaScript programming, asynchronous operations, promises, and data processing, which are useful for retrieving vegetable details and prices from APIs.

4. Learning PHP, MySQL & JavaScript

- Author: Robin Nixon

- Publisher: O'Reilly Media
- Purpose: This book is useful for understanding server-side programming, database connectivity, user authentication, and storing product, customer, and order details if the project uses PHP and MySQL.

5. Designing Data-Intensive Applications

- Author: Martin Kleppmann
- Purpose: This book provides a deeper understanding of data storage, database design, reliability, and data processing. These concepts can help when planning the product inventory and order management modules.

Note: Include only books that you have consulted or that are relevant to your chosen technology stack.
